Exam Advanced Programming (I00032)

June 17 2024

- This is a digital exam: **provide your answers in the file ap24.txt**. This file is in the folder (starting at "ThisPC") Documents\Exam. Do not move this file!
- In Documents\Exam you also find SaC and Clean modules to get you started with the exam questions. See instructions how to use them with the SaC (step 5) and Clean compiler (step 6).
- This exam is *closed book* (*gesloten boek*). Only this exam and the information provided on the machine can be used. This includes the SaC compiler and its documentation, as well as the Clean system.
- This exam consists of 5 assignments. The weight of the parts is indicated in the margin. You can obtain a maximum of 100 points. There is an appendix with the main types and combinators of iTask.
- Read the exam carefully. Do not hesitate to ask clarification (via the proctor) if an assignment is unclear.
- All functions and data-structures must be defined in correct SaC or Clean syntax.
- It is not required to hand in compiling and tested code. Show that you understand the concepts. Although you have compilers available, use this tooling wisely. Testing and debugging all code will probably cost you too much time.
- The workflow to use SaC and Clean looks like this:
 - 1. Start VSCode (e.g. via Windows Search: VSCode | Start VSCode |
 - 2. In the "Terminal" menu, select "New Terminal".
 - 3. In the terminal, next to "powershell", click the pop-up icon next to "+" (+3) and select "UbuntuSaC (WSL)".
 - 4. In the terminal, enter the command:

```
su - ap
```

A commandline prompt appears that starts with ap@.

- 5. In this directory you can create a SaC program, say main.sac, compile it with sac2c main.sac, and execute it via ./a.out. Warning: do not use the sac2c compiler flag -check c. You can use VSCode to open ("File" menu, command "Open File...") the SaC program by navigating to (starting at "ThisPC"):

 Documents\Ubuntu\rootfs\home\ap\.
- 6. For Clean and iTask you work in the folder itasks-template, so, in the same terminal enter: cd itasks-template
 - (a) In this directory you find the nitrile.yml file in which you set which Clean module to compile and where the executable is generated. It is currently set to the example iTask module HelloWorld.icl that you can find in the directory scr, and the executable is generated as bin/HelloWorld.
 - (b) You can use VSCode to open ("File" menu, command "Open File...") a Clean program by navigating to (starting at "ThisPC"):
 - Documents\Ubuntu\rootfs\home\ap\itasks-template\src\.
 - (c) In the itasks-template directory, compile your program with nitrile build and execute it by ./bin/HelloWorld.
 - (d) To test your running iTask application, open a browser and navigate to localhost: 8080. Do not forget to terminate the running program before recompiling an edited version.
 - (e) Remember that you are not connected to the internet. Hence, things like nitrile fetch will not work and can harm your project.

1 Array Programming

1.a) SaC supports a built-in selection operation _sel_VxA_ which takes two arguments, an integer vector and an array of arbitrary element type. Provided the vector length matches the dimensionality of the array and the elements of the integer vector are legal indices into the array, it returns the correspoding scalar value. Modify the following function definition using *type pattern* to express the argument constraints precisely. You may use existing functionality from the standard library to express the required constraints.

```
float select (int[.] v, float[*] a)
{
    return _sel_VxA_ (v, a);
}
```

- **1.b**) Write a different version of select that allows for shorter index vectors and returns the corresponding hyperplanes. For example, select ([1], [[0,1], [2,3]] should result in [2,3]. Again, make sure you express all argument constraints precisely.
- 1.c) Define a function concat that takes two integer vectors and appends them. You are **not(!)** allowed to use ++ from 5 pt. the standard library! Make sure you express all constraints on the signature precisely.
- 1.d) Extend your definition of concat so that you allow for higher-dimensional arrays as arguments, provided that 5 pt. all shape components of the two arrays that follow the first dimension are identical. For example, concat ([[1,2,3]], [[4,5,6],[7,8,9]]) should yield [[1,2,3],[4,5,6],[7,8,9]]
- 1.e) Create a ranked version r_concat, which takes a scalar integer as additional first argument. This argument should indicate which dimension is to be concatenated. We should have: r_concat (0,a,b) == concat (a,b) for any set of legal arguments a and b of concat.

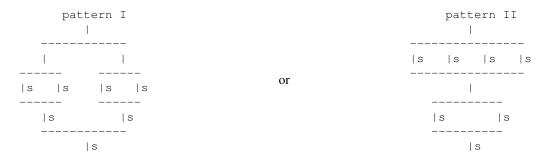

As another example, consider r_{concat} (1, [[1,2],[3,4]], [[5,6,7],[8,9,10]]) which should result in [[1,2,5,6,7],[3,4,8,9,10]].

2 Concurrency Pattern in SaC

Consider the following SaC code:

```
int ssum (int[m] v)
{
    s = 0;
    for (i=0; i < m; i++)
        s += v[i];
    return s;
}
int ssum (int[m,r:shp] a)
{
    b = {[i] -> ssum (a[i])};
    return ssum (b);
}
int main()
{
    a = iota(8);
    return ssum (reshape ([2,2,2], a));
}
```

2.a) Which of the two concurrency pattern below does this code exhibit? NB: the symbols s indicate sequential summations.

- 2.b) Re-implement the second instance of ssum so that it implements the other pattern!
- **2.c**) Which of the two patterns do you expect to be more efficient, assuming we would run it on a much larger array? 10 pt. Provide arguments based on the concurrency pattern.

10 pt.

3 WHILE + arrays

In this assignment we work with the WHILE programming language. See Appendix A for one of the versions defined in the lecture.

For the evaluation of WHILE style programs, we introduce the following data types:

```
:: State :== 'Data.Map' .Map Var Dynamic
:: Var :== String
:: Result a = Result a | Error String
:: Eval a =: E (State → (Result a, State))
```

Evaluation of expressions and statements can fail, which is captured with the Result type: a successful evaluation with value x produces (Result x), whereas a failing evaluation yields an error message msg as (Error msg).

State uses the efficient key-value pair implementation Data. Map to associate the value, stored as a Dynamic, of a variable, represented with the type Var. Access to the state is provided with the operations write and read:

```
write :: Var a \to Eval () | TC a write v = E \lambda s = (Result (), 'Data.Map'.put v (dynamic a) s)

read :: Var \to Eval a \mid TC a

read v = E \lambda s = case' Data.Map'.get v s of

?Just (x :: a^{\circ}) = (Result x, s)

?Just (x :: a^{\circ}) = (Error ("read: var " <+ v <+ " has wrong type"), s)

<math>(Error ("read: var " <+ v <+ " is undefined"), s)
```

3.a) Implement the instances for the monadic type constructor classes, such that they adhere to the usual laws (you do 5 pt. not have to prove this):

```
instance pure Eval where instance Monad Eval where instance Functor Eval where instance <*> Eval where instance MonadFail Eval where
```

- **3.b**) We extend the WHILE DSL with support for arrays. The following language elements are added to expressions:
 - VarA v: variable v refers to an array.
 - Gen low up: generates an array with first element (at index 0) having the value from expression low and last element having the value from expression up (in case low exceeds up, an error result should be generated that an array cannot be empty).
 - Select i arr: select element at index from expression i in the array from expression arr (in case of an index out of bounds error, an error result should be generated).

and the statements are extended with an array element update:

• Upd v i x: replaces element at index from expression i in array variable v with the value from expression x (in case of an index out of bounds error, an error result should be generated).

Please note that for this assignment it is not required to use Clean arrays, Clean lists will do. Generating a Clean list with bound values low and up is done with [low..up]; selecting the element at index j from list l is done with 1!!j, and updating an element at index j to a new value x in list l is done with updateAt j x l.

Fix the type Expr a given in Appendix A by adding the BM bi-maps needed for type-safe evaluation and extend it with cases for VarA, Gen, and Select. Extend the type Stmt with the case Upd.

3.c) Implement a monadic evaluator for expressions that deals with errors. It must have the following signature:

```
evalE :: (Expr a) State \rightarrow Eval a | TC a
```

3.d) Implement a monadic evaluator for statements Stmt. It must have the following signature:

8 pt.

8 pt.

8 pt.

```
evalS :: Stmt \rightarrow Eval ()
```

4 Shallow and Tagless DSL

In this assignment we improve the WHILE DSL by enforcing type safe variables and offering multiple views. We introduce a new type Var' for variables and add an operation to the Evaluator to obtain a fresh variable name:

An initial framework for the shallow and tagless WHILE DSL is given below. Finish all the missing components (...) 8 pt. of the framework.

```
class expr v
where lit
                      :: a \rightarrow v a
                      :: (va) (va) \rightarrow va | + a
     add
      sub
                      :: (v a) (v a) \rightarrow v a \mid -a
                      :: (v a) (v a) \rightarrow v Bool | < a
                      :: (v Bool) \rightarrow v Bool
      neg
                     :: ... // the shallow, tagless version of Gen
      gen
      sel
                      :: ... // the shallow, tagless version of Select
class vars v a
                     :: (Var'a) 
ightarrow v a
where var
                 :: ... // the shallow, tagless version of variable binding
      def
      (.=.) infixr 2 :: \dots // the shallow, tagless version of =.
where (.:.) infixr 1:: (v a) (v b) \rightarrow v b
                  :: ... // the shallow, tagless version of Upd
      upd'
      if'
                     :: (v Bool) (v a) (v a) 
ightarrow v a
      while'
                    :: (v Bool) (v a) \rightarrow v ()
      skip'
                    :: v ()
:: In a b = In infix 0 a b
instance expr Eval
   where lit x = pure x
        add e1 e2 = e1 \gg = \lambda v1 = e2 \gg = \lambda v2 = pure (v1 + v2)
         sub e1 e2 = e1 >>=\lambdav1 = e2 >>=\lambdav2 = pure (v1 - v2)
         leq e1 e2 = e1 \gg=\lambdav1 = e2 \gg=\lambdav2 = pure (v1 \leq v2)
                  = e \gg = \lambda vb = pure (not vb)
         neg e
         aen ...
         sel ...
instance vars Eval a | TC a
   where var ...
         def ...
         (<u>.=.</u>) ...
instance stmt Eval
   where (.:.) s t = s >>= \lambda_ = t
         if' c t e = c>>=\lambdab = if b t e
         while'cb=if'c(b.:.while'cb) skip'
         skip'
                    = pure ()
         upd' ...
```

5 Task Oriented Programming

In this assignment we create a couple of tasks to allow people to chat with each other. For the chat, a shared data source is globally accessible:

```
chatsSDS :: SimpleSDSLens [Message]
chatsSDS = sharedStore "chats" []
```

A message contains information about when the message is created (roughly), the sender, the receivers, and message text:

derive class iTask Message

An initial implementation module TOP.icl is available to get you started. You still need to copy your answers to the answer file as instructed in the preamble of this exam text.

5.a) Implement the task function:

3 pt.

```
returnIf :: (Task a) (a \rightarrow Bool) \rightarrow Task a | iTask a
```

(returnIf t p) evaluates t, and as soon as t has a (stable or unstable) task value (TaskValue x $_$) for which predicate (p x) evaluates to True, then (returnIf t p) returns x.

5.b) Implement the task function:

3 pt.

```
\texttt{enterMessage} \, :: \, \texttt{[User]} \, \to \, \texttt{Task Message}
```

(enterMessage users) lets the current user (available from the SDS currentUser) generate a new message that contains the current date and time (available from the SDS currentDateTime), a *non-empty* subset of users, and a *non-empty* message text. If these conditions hold, then the created message is returned as a stable task value.

5.c) Implement the task function:

3 pt.

```
\verb|addMessage:: [User] (SimpleSDSLens [Message])| \rightarrow \\ \verb|Task [Message]|
```

(addMessage users sds) lets the current user create a new message (with (enterMessage users)) and adds that message with an $atomic\ update$ to the argument SDS sds.

5.d) Implement the task function:

4 pt.

```
\texttt{session} :: \texttt{[User]} \texttt{ (SimpleSDSLens [Message])} \rightarrow \texttt{Task ()}
```

(session users sds) lets every user in users perform the task that views the current content of the given SDS sds, and offers them two actions:

- 1. *New message:* at all times it is possible for the user to create a new message and add it to sds. This can be repeated arbitrarily many times.
- 2. Stop: at all times it is possible for the user to stop participating in the session.

A While

In this appendix you find the deeply embedded representation of the WHILE language without the BM bi-maps.

```
:: Expr a
= Lit a
| Var
           Var
| Plus
          (Expr Int) (Expr Int)
| Not
          (Expr Bool)
          (Expr Bool) (Expr Bool)
| And
|∃b:Leq (Expr b) (Expr b) & <, TC b
:: Stmt
= (=.) infix 2 Var (Expr Int)
| (:.) infixr 1 Stmt Stmt
| If (Expr Bool) Stmt Stmt
| While (Expr Bool) Stmt
| Skip
:: BM a b = {ab :: a \rightarrow b, ba :: b \rightarrow a}
bm = \{ab = id, ba = id\}
```

A program that creates an array and reverses it looks similar to this:

```
reverse :: Int Int \rightarrow Stmt
reverse low up
  = "low" =. Lit low :.
    "up" = Lit up :.
    "data" =. Gen (Var "low") (Var "up") :.
                                                         // data = [low..up]
    "i" =. Sub (Var "up") (Var "low") :.
                                                         //i = up - low
    "j" =. Lit 0 :.
                                                         //j = 0
   While (Leq (Var "j") (Var "i")) (
                                                         // while (j \leq i) {
      // data[j] = y
      Upd "data" (Var "j") (Var "y") :.
      "i" =. Sub (Var "i") (Lit 1) :.
                                                         // i = i - 1
      "j" =. Add (Var "j") (Lit 1)
                                                         // j = j + I
                                                         // }
    )
```

B Clean

```
// Monad and friends. Import these definitions as
import Control.Monad, Control.Monad.Fail, Control.Applicative, Data.Functor
class pure :: a \rightarrow f a
class Functor f
where fmap :: (a \rightarrow b) (f a) \rightarrow f b
       (\$) infixl 4 :: (a \rightarrow b) (f a) \rightarrow f b | Functor f
